Assignment 1

Isaac Davis

2023-08-03

8.1

1. Create a vector of three elements (2,4,6) and name that vector vec_a. Create a second vector, vec_b, that contains (8,10,12). Add these two vectors together and name the result vec_c.

```
vec_a <- c( 2, 4, 6 )
vec_b <- c( 8, 10, 12 )
vec_c <- vec_a + vec_b
vec_c</pre>
```

[1] 10 14 18

8.2

2. Create a vector, named vec_d, that contains only two elements (14,20). Add this vector to vec_a. What is the result and what do you think R did (look up the recycling rule using Google)? What is the warning message that R gives you?

```
vec_d <- c( 14, 20 )
vec_a + vec_d</pre>
```

```
## Warning in vec_a + vec_d: longer object length is not a multiple of shorter
## object length
```

```
## [1] 16 24 20
```

R has a recycling rule where if two vectors are attempted to be added together that are not the same length, it will keep replicating the smaller one. R warned me of this using this warning: Warning: longer object length is not a multiple of shorter object length

8.3

3. Next add 5 to the vector vec_a. What is the result and what did R do? Why doesn't in give you a warning message similar to what you saw in the previous problem?

```
vec_a + 5
```

```
## [1] 7 9 11
```

It simply added 5 to each value in the vector.

8.4

4. Generate the vector of integers $\{1, 2, \dots 5\}$ in two different ways.

```
8.4.a
```

```
a) First using the `seq()` function seq( from=1, to=5, by=1 )
```

```
## [1] 1 2 3 4 5
```

8.4.b

b) Using the `a:b` shortcut.

```
c(1:5)
```

```
## [1] 1 2 3 4 5
```

8.5

- 5. Generate the vector of even numbers $\{2,4,6,\ldots,20\}$
 - a) Using the seq() function and ### 8.5.a

```
seq( from=2, to=20, by=2 )
```

```
## [1] 2 4 6 8 10 12 14 16 18 20
```

b) Using the a:b shortcut and some subsequent algebra. *Hint: Generate the vector 1-10 and then multipl

8.5.b

```
c(1:10) * 2
```

[1] 2 4 6 8 10 12 14 16 18 20

8.6

6. Generate a vector of 21 elements that are evenly placed between 0 and 1 using the seq() command and name this vector \mathbf{x} .

```
x <- seq( from=0, to=1, length.out=21 )
x</pre>
```

```
## [1] 0.00 0.05 0.10 0.15 0.20 0.25 0.30 0.35 0.40 0.45 0.50 0.55 0.60 0.65 0.70 ## [16] 0.75 0.80 0.85 0.90 0.95 1.00
```

8.7

7. Generate the vector $\{2,4,8,2,4,8,2,4,8\}$ using the rep() command to replicate the vector c(2,4,8).

```
rep(c(2, 4, 8), 3)
```

```
## [1] 2 4 8 2 4 8 2 4 8
```

8.8

8. Generate the vector {2, 2, 2, 2, 4, 4, 4, 4, 8, 8, 8, 8} using the rep() command. You might need to check the help file for rep() to see all of the options that rep() will accept. In particular, look at the optional argument each=.

```
rep( c( 2, 4, 8 ), each=4 )
```

```
## [1] 2 2 2 2 4 4 4 4 8 8 8 8
```

8.10

10. In this problem, we will work with the matrix

$$\begin{bmatrix} 2 & 4 & 6 & 8 & 10 \\ 12 & 14 & 16 & 18 & 20 \\ 22 & 24 & 26 & 28 & 30 \end{bmatrix}$$

8.10.a

a) Create the matrix in two ways and save the resulting matrix as `M`.

8.10.a.i

i. Create the matrix using some combination of the `seq()` and `matrix()` commands.

```
M <- matrix( seq( from=2, to=30, by=2 ),</pre>
              nrow=3, byrow=TRUE )
Μ
##
         [,1] [,2] [,3] [,4] [,5]
## [1,]
                                  10
## [2,]
                            18
                                  20
           12
                 14
                      16
## [3,]
           22
                 24
                      26
                            28
                                  30
```

8.10.a.ii

ii. Create the same matrix by some combination of multiple `seq()` commands and either the `rbind()

```
## [1,]
            2
                  4
                        6
                              8
                                   10
## [2,]
           12
                 14
                             18
                                   20
                       16
                 24
## [3,]
           22
                       26
                             28
                                   30
```

8.10.b

b) Extract the second row out of `M`.

```
M[2,]
```

```
## [1] 12 14 16 18 20
```

8.10.c

c) Extract the element in the third row and second column of `M`.

```
M[3, 2]
```

[1] 24

8.12

12. The following code creates a data.frame and then has two different methods for removing the rows with NA values in the column Grade. Explain the difference between the two.

```
df <- data.frame( name= c( 'Alice', 'Bob', 'Charlie', 'Daniel' ),</pre>
                  Grade = c(6, 8, NA, 9)
df[ -which( is.na(df$Grade) ), ]
##
       name Grade
## 1 Alice
                6
## 2
        Bob
                8
## 4 Daniel
df[ which(!is.na(df$Grade)),]
##
       name Grade
## 1
     Alice
                6
## 2
        Bob
                8
## 4 Daniel
The first one deletes NA rows, the second one grabs non NA rows.
8.14
 14. Create and manipulate a list. ### 8.14.a
      a) Create a list named my.test with elements
           • x = c(4,5,6,7,8,9,10)
           • y = c(34,35,41,40,45,47,51)
           • slope = 2.82
           • p.value = 0.000131
my.test <- list( x=c(4, 5, 6, 7, 8, 9, 10),
                  y=c(34, 35, 41, 40, 45, 47, 51),
                  slope=2.82,
                  p.value=0.000131 )
my.test
## [1]
       4 5 6 7 8 9 10
##
## $y
## [1] 34 35 41 40 45 47 51
##
## $slope
## [1] 2.82
## $p.value
## [1] 0.000131
8.14.b
b) Extract the second element in the list.
my.test[2]
## $y
## [1] 34 35 41 40 45 47 51
```

8.14.c

c) Extract the element named `p.value` from the list.

```
my.test['p.value']
## $p.value
```

9.1

[1] 0.000131

1. Download from GitHub the data file Example_5.xls. Open it in Excel and figure out which sheet of data we should import into R. At the same time figure out how many initial rows need to be skipped. Import the data set into a data frame and show the structure of the imported data using the str() command. Make sure that your data has n=31 observations and the three columns are appropriately named. If you make any modifications to the data file, comment on those modifications.

```
data <- readxl::read_excel( './Example_5.xls', sheet='RawData', range="A5:C36" )
str( data )

## tibble [31 x 3] (S3: tbl_df/tbl/data.frame)
## $ Girth : num [1:31] 8.3 8.6 8.8 10.5 10.7 10.8 11 11 11.1 11.2 ...
## $ Height: num [1:31] 70 65 63 72 81 83 66 75 80 75 ...
## $ Volume: num [1:31] 10.3 10.3 10.2 16.4 18.8 19.7 15.6 18.2 22.6 19.9 ...</pre>
```

9.2

2. Download from GitHub the data file Example_3.xls. Import the data set into a data frame and show the structure of the imported data using the tail() command which shows the last few rows of a data table. Make sure the Tesla values are NA where appropriate and that both -9999 and NA are imported as NA values. If you make any modifications to the data file, comment on those modifications.

```
data <- readxl::read_excel( './Example_3.xls', sheet='data', range="A1:L34", na=c( "-9999", "NA" ) )
tail( data )
## # A tibble: 6 x 12
##
     model
                           cyl
                                disp
                                         hp
                                             drat
                                                          qsec
                                                                  vs
                                                                         am
                                                                             gear
                                                                                   carb
                     mpg
     <chr>
                   <dbl> <dbl> <dbl>
                                      <dbl>
                                            <dbl>
